SUMMARY:
Buckling-restrained braces (BRBs) are widely used in seismic countries as ductile seismic-resistant elements and energy dissipating elements. One of the key limits of BRBs is overall flexural buckling, and they are required to exhibit stable hysteresis under cyclic axial loading with out-of-plane drifts, their stability under such conditions being essential. However, many researches are indicating that there are risks of overall buckling including connections before the BRBs yield. In this paper, the stability conditions of BRBs including their connections are discussed based on cyclic loading tests with out-of-plane drifts, and a unified simple equation for evaluating their stability is proposed.

Keywords: Buckling-restrained brace, Connections, Cyclic loading, Buckling, Stability condition

1. INTRODUCTION

Buckling-restrained braces (BRBs) are expected to exhibit stable hysteresis under cyclic axial loading with out-of-plane drifts, and their stability under such conditions is essential. However, many researchers have indicated that there are risks of overall buckling including connections before the braces yields, when plastic hinges are introduced at the ends of the restrainers (Fig.1.1). In this paper, the stability conditions of BRBs including their connections are discussed and equations evaluating such conditions are proposed. Cyclic axial loading tests of BRBs with initial out-of-plane drift are carried out, and the validity of the proposed equation is confirmed.

Figure 1.1. Overall Buckling of BRB including connections

Figure 2.1. BRB Stability Condition
2. STABILITY CONDITION FOR BRBS INCLUDING CONNECTIONS

In AIJ Recommendation for Stability Design of Steel Structures (2009), following two concepts for BRB design to sustain stability including connections are indicated, as shown in Fig.2.1.

1) Plastic hinges are allowed at the restrainer-ends, and the stability conditions are given for the restrained part and connections individually [Fig.2.1(a)].

2) Bending moment transfer is expected at the restrainer-ends, and composite stability of the restrained part and connections is confirmed [Fig.2.1(b)]. Pin-ends types are included in this category.

For the concept 1), the following equations are proposed by Kinoshita et.al (2007).

The stability condition of the restrained part;

\[ M_{cr}^B \geq \frac{a_r N_{cu}}{1-N_{cu}/N_{cr}} \]  (2.1)

The stability condition of connections;

\[ N_{cr}^c = \frac{(1-2\xi)\gamma BjEI_B}{(2\xi L_0)^2} > N_{cu} \]  (2.2)

where, \( M_{cr}^B \): bending strength of the restrainer; \( a_r \): expected imperfections; sum of \( a \) (restrainer imperfection), \( e \) (axial force eccentricity), and \( s_r \) (clearance between core and restrainer); \( N_{cu} \): maximum axial force of core plates, normally estimated 1.2-1.5 times of yield force of the core plate including hardening; \( N_{cr}^c \): Euler buckling strength of the restrainer; \( \gamma jEI_B \): Bending stiffness of the connections; and \( \xi L_0 \): connection length.

This concept is based on the condition that the ends of the connections are rigidly fixed against rotation; however, very stiff gusset plates are required to satisfy this condition. For example, a stiffened gusset plate as in Fig.2.2 (c) is essential. Moreover, preventing the rotation of the beam where BRBs are connected, large stiffening beam in out-of-plane directions are required as shown in Fig.2.3.

The other design concept of BRBs is the transfer of bending moment at the restrainer-ends as in the concept 2) in AIJ recommendation, which confirm the stability of the restrained part and the connections compositely as shown in Fig.2.1(b). Tekeuchi et.al (2009) indicated that the restrainer-ends can transfer the bending moment up to the bending strength of the restrainer or stiffened core section, if the stiffened ends of the core plates are inserted into the restrainer by more than two times the core plate width (\( L_{in} > 2B_c \) in Fig.2.4(a)). Where, they produce an initial imperfection \( a_r = a + e + s_r + (2s_r / L_{in})\xi L_0 \) (Fig.2.4(b)) and the process of overall buckling can be described by a simple model as in Fig. 2.5.

As in the figures, the BRB are modelled as a bending element with rotational springs \( K_{RG} \) (\( K_{RG} = 0 \) for pin-ends) at both ends and initial imperfection \( a_r \). When the bending moment reaches the bending strength of the restrainer-ends \( M_{cr}^B \), the brace collapses. Firstly, the ends of the connections are assumed to be rigid (\( K_{RG} = \infty \)) and out-of-plane deformations of the connections in the mechanism phase are assumed to be cosine curves as in Fig.2.5(a);

\[ y = \frac{a_r}{\xi L_0} + y_r \left[ 1 - \cos \left( \frac{\pi x}{2\xi L_0} \right) \right] \]  (2.3)

Then the strain energy stored in both connection is;

\[ U_0 = 2\int_0^L \frac{\gamma jEI}{2} \left( \frac{d^2 y}{dx^2} \right)^2 \, dx = \frac{\pi^4 \gamma j EI y_r^2}{32(\xi L_0)^2} \]  (2.4)
The rotation angle of the plastic hinges is:

$$\Delta \theta = \frac{dy}{dx}|_{x=L_0} - \frac{\alpha_y}{\xi L_0} = \frac{\pi}{2\xi L_0} y_r$$  \hspace{1cm} (2.5)

Then the plastic strain energy stored in the hinges are;

$$U_p = 2M_p' \Delta \theta = \frac{\pi y_r^2}{\xi L_0} M_p'$$  \hspace{1cm} (2.6)

The axial deflection is;

$$\Delta u_a = 2 \left[ \frac{1}{2} \int_0^L \left( \frac{dy}{dx} \right)^2 - \left( \frac{\alpha_y}{\xi L_0} \right)^2 \right] dx = \frac{\pi^2 y_r^2}{8 \xi L_0} + \frac{2a_y y_r}{\xi L_0}$$  \hspace{1cm} (2.7)

The work done is;

$$T = N \Delta u_a = \frac{\pi^2 (y_r^2 + 16a_y y_r/\pi^2)}{8 \xi L_0} N$$  \hspace{1cm} (2.8)

with the principle of stationary total potential energy;

$$\frac{\partial (U_p + U_p - T)}{\partial y_r} = \frac{\pi^4 \gamma_p E I y_r}{16 (\xi L_0)^3} + \frac{\pi y_r M_p'}{\xi L_0} - \frac{\pi^2 (y_r^2 + 16a_y y_r/\pi^2)}{8 \xi L_0} N_{\sigma} = 0$$  \hspace{1cm} (2.9)

$$N_{\sigma} = \frac{\pi^2 \gamma_p E I y_r}{(2\xi L_0)^3} y_r + \frac{4 M_p'}{\pi y_r + a_y}$$  \hspace{1cm} (2.10)

Approximating $8/\pi^2$ as 1, we obtain the following.

$$N_{\sigma} \approx \frac{\pi^2 \gamma_p E I y_r}{(2\xi L_0)^3} y_r + \frac{4 M_p'}{\pi y_r + a_y}$$  \hspace{1cm} (2.11)

Similar calculation can be carried out in an asymmetrical mode as shown in Fig.2.5(b), as follows.

---

**Figure 2.4.** Bending Moment Transfer at Restrainer End

(a) Detail (b) Model

**Figure 2.5.** Overall Buckling with Rotational Springs

(a) Symmetrical (b) Asymmetrical (c) One-side

**Figure 2.6.** Assumed Process of Overall Buckling

(a) Symmetric mode (b) Asymmetric mode

**Figure 2.7.** Additional Bending Moment by Out-of-plane Drift
\[ U_r = \frac{\pi y_r \pi - 2 \pi \xi + 4 \xi}{\xi L_0} M' \]  
\[ T = \frac{\pi^2 N}{8 \xi(1 - 2 \xi) L_0} (y_r^2 + 16 \xi a_y / \pi^2) \]  
\[ N_{cr} = \frac{\pi^2 (1 - 2 \xi) y_r E I y_r}{(2 \xi L_0)^2} y_r + 8 a_y / \pi^2 + \frac{4(1 - 2 \xi + 4 \xi / \pi)}{\pi (y_r + 8 a_y / \pi^2)} M' \]  
When \( \xi = 0.25 \), it can be approximated as follows:  
\[ N_{cr} \approx \frac{\pi^2 (1 - \xi) y_r E I y_r}{(2 \xi L_0)^2} y_r + a_y + M' \]  
When \( M' = 0 \) and \( a_y << y_r \), Eq.(2.15) approaches Eq.(2.2). As indicated by Eqs.(2.11) and (2.15), the overall buckling strength is determined by the asymmetrical mode when the ends of the connections are rigidly fixed.

Next, consider rotational stiffness \( K_{Rg} \). Define normalized rotational stiffness \( \kappa_{Rg} \) as follows:  
\[ \kappa_{Rg} = \frac{K_{Rg} \xi L_0}{y_r E I} \]  
As in Fig.2.5(a), additional deformation by the rotation of the end spring is defined as \( y_{rs} \). As deformation by connection bending \( y_{re} \) become equivalent to \( y_{rs} \) when \( \kappa_{Rg} = 3 \), the strain energy stored in the springs is estimated as:  
\[ U_s = \frac{y_{rs} E I y_r^2}{32(\xi L_0)^2} \left( \frac{\kappa_{Rg}}{\kappa_{Rg} + 3} \right)^2 \]  
The spring rotation \( \Delta \theta_s \), plastic hinge rotation \( \Delta \theta_r \), and axial deformation can be expressed as follows:  
\[ \Delta \theta_s = \frac{y_{rs} \pi \xi L_0}{\xi L_0 \kappa_{Rg} + 3} \]  
\[ \Delta \theta_r = \frac{y_r \kappa_{Rg} + 6}{2 \xi L_0 \kappa_{Rg} + 3} \]  
\[ \Delta u = \frac{y_r^2 + 2 a_y y_r}{\xi L_0} + \frac{3}{\kappa_{Rg} + 3} + \frac{\pi^2}{16} \frac{\kappa_{Rg} + 24 / \pi^2}{\kappa_{Rg} + 3} \]  
Now the energy stored in the springs and hinges and the works done can be evaluated, respectively:  
\[ U_s = \frac{y_{rs} E I y_r \kappa_{Rg}}{(\xi L_0)^2} \left( \frac{3}{\kappa_{Rg} + 3} \right)^2 \]  
\[ U_r = \frac{y_r \pi \kappa_{Rg} + 6}{\xi L_0 \kappa_{Rg} + 3} M' \]  
\[ T = \frac{\pi^2 (y_r^2 + 2 a_y y_r) \kappa_{Rg} + 24 / \pi^2}{8 \xi L_0 \kappa_{Rg} + 3} N \]  
From the condition \( \partial(U_s + U_r - T) / \partial y_r = 0 \),  
\[ N_{cr} \approx \frac{\pi^2 y_r E I y_r \kappa_{Rg}}{(2 \xi L_0)^2} \left( \frac{\kappa_{Rg} + 24 / \pi^2}{\kappa_{Rg} + 3} + \frac{4}{\pi} \frac{M'}{y_r + a_y} \right) \]  
In the above equation (2.24) become Eq.(2.25) when the connection ends are pinned (\( \kappa_{Rg} = 0 \)).  
\[ N_{cr} = \frac{M'}{y_r + a_y} \]  
On contrary, Eq.(2.11) can be restored when \( \kappa_{Rg} = \infty \). Hence Eq.(2.24) covers symmetrical buckling strength for various rotational stiffness from pin-ends to rigid-ends. Asymmetrical strength can be derived by similar process as:  
\[ N_{cr} \approx \frac{\pi^2 (1 - 2 \xi) y_r E I y_r}{(2 \xi L_0)^2} \left( \frac{\kappa_{Rg} + 24 / \pi^2}{\kappa_{Rg} + 3} + \frac{4}{\pi} \frac{M'}{y_r + a_y} \right) \]
Similarly, strength for one-side buckling mode as shown in Fig.2.5(c) can be derived as follows.

\[
N_{cr} = \pi^2 (1-2\xi) y_j EI \left( \frac{\kappa_{Rg}}{(2\xi L_0)} \right)^2 \frac{y_r}{(1-\xi)\kappa_{Rg} + 24/\pi^2} \frac{y_r + a_r}{y_r + a_r} + \frac{M_p}{y_r + a_r}
\]

(2.27)

Eqs.(2.26), (2.27) approaches Eq.(2.25) when \( \kappa_{Rg} = 0 \) and Eq.(2.15) when \( \kappa_{Rg} = \infty \), also covering asymmetrical buckling strength for various rotational stiffness. Eq.(2.26) gives slightly lower values than Eq.(2.27). Eqs.(2.24), (2.26) and (2.27) all indicate that the axial force decreases as the out-of-plane displacement \( y_r \) increases. When the elastic axial force and out-of-plane displacement relationship expressed by Eq. (2.28) reaches this condition, the brace is considered to be collapsed [Fig.2.6(a)].

\[
N = \frac{y_r}{a_r} N_{cr}^B = \frac{y_r}{a_r} N_{cr}^B + N_r
\]

(2.28)

where, \( N_{cr}^B \) is overall elastic buckling strength which can be derived as follows.

\[
N_{cr}^B = \frac{4\pi^2 EI}{L_0^2 (1-2\xi)} \left( \frac{\kappa_{Rg}}{\kappa_{Rg} + 10(\kappa_{Rg} + 16)} \right) \left( \frac{\kappa_{Rg} + 14(\kappa_{Rg} + 64)}{\kappa_{Rg}} \right)
\]

(2.29)

Substituting \( y_r = a_r N/(N_{cr}^B - N) \) into Eq. (2.26), the required bending strength \( M_p \) can be derived as follows:

\[
M_p = \frac{a_r}{1-N/N_{cr}^B} \left[ \frac{\pi^2 (1 - 2\xi) y_j EI}{(2\xi L_0)^2} \frac{y_r}{(1-\xi)\kappa_{Rg} + 24/\pi^2} \frac{y_r + a_r}{y_r + a_r} \right] = \frac{a_r}{1-N/N_{cr}^B} \left[ N - N_r \right]
\]

(2.30)

When the structure deforms out-of-direction not only axial deformation, additional bending moment is distributed as in Fig.2.7. The initial bending moment at the restrainer-end \( M_0 \) can be estimated as;

\[
M_0 = \frac{\delta_0 - 2s \cdot (1 + 2\xi)}{L_0} \geq 0
\]

(2.31)

where, \( \delta_0 \) is expected story drift in an out-of-plane direction.

Bending moment strength at restrainer-ends are considered to be reduced by this initial moment. Consequently, the stability condition can be expressed as follows, with the condition that the cross point of Eqs.(2.28) and (2.30) (see Fig.2.8) exceeds the expected maximum axial force \( N_{cu} \).

\[
M_p - M_0 \geq \frac{a_r}{1-N/N_{cr}^B} \left[ N_{cr} - N_r \right] \quad \text{where,} \quad M_p - M_0 \geq 0
\]

(2.32)

where, \( M_p \) : Ultimate bending strength of restrainer-ends, \( M_0 \) : Initial bending moment at restrainer- ends [Eq.(2.31)], \( a_r \) : Initial imperfections = \( a + e + s + (2s_r/L_0)\xi L_0 \), \( N_{cr} \): Expected maximum axial force of BRB = Yield force multiplied by hardening factor, \( N_{cr}^B \): Elastic overall buckling strength [Eq.(2.29)], \( N_{cr}^P \) : Elasto-plastic buckling strength caused by connections using the following equivalent slenderness ratio by Eq.(2.33). In this equation (2.33), \( \xi' \) in Fig.2.4(b) instead of \( \xi \) should be used estimating plastic hinges can be produced at the neck of the reinforced zone of the core plate.

\[
\lambda_r = \frac{2\xi' L_0}{I} \left( \frac{\kappa_{Rg} + 24/\pi^2}{(1-2\xi') \kappa_{Rg}} \right)
\]

(2.33)

where \( N_{cr}^P \) must satisfy the following limit to prevent the yielding at outer ends of the gusset plates:

\[
N_{cr}^P \leq N_{cr}^P = \frac{1}{a_r} \left[ \frac{M_p}{M_{cr} - (1 - 2\xi')} \right]
\]

(2.34)

where, \( M_{cr} \): Bending strength of the outer ends of the gusset plates including the effect of axial force.

To satisfy Eq.(2.32), two approaches can be used for BRB design.

1) Decrease \( M_p \) and \( N_{cr}^P \) by decreasing \( \kappa_{Rg} \), and provide enough bending strength \( M_p \) at the restrainer-end. This concept corresponds to transferring bending moment at the restrainer-ends. [Fig.2.1(b)].

2) When \( \kappa_{Rg} \) is large, the left part of Eq.(2.32) becomes small or zero, so satisfy Eq.(2.32) by designing \( N_{cr}^P \) larger than \( N_{cu} \). This concept corresponds to Eq.2 which allows hinges at the restrainer-ends. [Fig.2.1(a)].

As above, Eq.(2.32) covers both design concepts discussed in Fig.2.1.
3. CYCLIC LOADING TEST OF BRB WITH OUT-OF-PLANE DISPLACEMENT

To confirm the stability including the connections, cyclic loading tests of the BRB with out-of-plane displacement are carried out. The test configuration with specimens is shown in Figs.3.1 and 3.2, the loading program are shown in Fig.3.3, and the test matrix is shown in Table 3.1. The core plates are JIS-SN400B (average yield strength: 270MPa) 12mm thick and 90mm wide, the restrainers are mortar in-filled box section of 125mm square and 2.3mm thick or circular tube of 139.8 dia. and 3.2mm thick. The insert length of the stiffened part of the core plates into the restrainers \( L_{in} \) can be 180mm, 90mm, 45mm, which is 2.0 times, 1.0 times and 0.5 times of the core width, respectively. In addition, the clearance between the core plate and the restrainers are varied from 1.0mm to 2.0mm, and 6 different specimens are tested. The specimens are labelled as M-(R:Rectangular, C:Circular)-L(Insert length ratio) -S-(Clearance). The same gusset plates are used in all specimen which have a small rotational stiffness \( \kappa_{Rg} \approx 0.04 \). Initial imperfection angles in each specimen are summarized in Table 3.2.
Before the test, out-of-plane deformation equivalent to the story drift of 1% radian is applied to each specimen, and then axial cyclic deformation equivalent up to 1-3% of the plastic length of the core plate is applied. This normalized axial strain is roughly equivalent to in-plane story drift angle. The hysteresis loops obtained for each specimen are shown in Fig.3.4 to Fig.3.10.

MRL2.0S1 (Fig.3.4) showed stable hysteresis up to 12 cycles of 3% normalized strain, until out-of-plane instability appeared. This performance is considered to be satisfactory for energy-dissipation braces. MRL2.0S2 (Fig.3.5) which has slightly larger initial imperfection than previous one, showed stable hysteresis until 3 cycles up to 3% normalized strain, then out-of-plane instability appeared. MCL2.0S2 (Fig.3.6) is constituted by a circular mortar in-filled steel tube, showed stable hysteresis until 2 cycle up to 2% normalized strain, until appearance of out-of-plane instability. MRL1.0S1 (Fig.3.7) reached the yield strength of the core plate and showed stable hysteresis up to the 2nd cycle of 1.0% normalized strain, then experienced overall buckling hinged at the restrainer-ends. MRL1.0S2 (Fig.3.8 and Fig.3.10) showed a hysteresis loop for only one cycle of 0.5% normalized strain, then experienced overall buckling hinged at the restrainer-ends. MCL1.0S2 (Fig.3.9) exhibited a hysteresis loop for only one cycle of 0.5 normalized strain, then undergoes overall buckling hinged at the restrainer-ends.

4. COMPARISON WITH THE PROPOSED EQUATION

These test results indicate that the stabilities of BRBs are strongly affected by the insert length ratio and clearance, which is expected from the proposed Eq.(2.32). In the following, each specimen is evaluated using Eq.(4.2). Takeuchi et.al (2009) proposed the following equations for the tested types of BRB:

\[ M_p^{\text{rest}} = \frac{\min \{ M_p^{\text{rest, rect}}, M_p^{\text{rest, circ}} \} }{M_p^{\text{rest, rect}}} \]

\[ M_p^{\text{rest, rect}} = \begin{cases} \min \{ Z_p^{\sigma_y}, K_{\text{ext-2}} \theta_s \} & \text{(Rectangular Tube)} \\ \min \{ Z_p^{\sigma_y}, K_{\text{ext-1}} \theta_s \} & \text{(Circular Tube)} \end{cases} \]

**Figure 4.1.** Axial Force vs. Out-of-plane Displacement
unsatisfactory from Eq.(2.32). All other specimens have much lower values, which indicate that their overall stabilities are not guaranteed. In total, the given safety values satisfactory estimate the performance of each specimen obtained in the cyclic loading tests and therefore are considered to be valid. Fig.4.1 shows the measured axial force-displacement relationships compared with the equations discussed in Sec.2. The test results are well estimated by the proposed equations so the proposed equations are considered to be valid.

5. CONCLUSIONS

The overall stabilities of BRBs are discussed and confirmed by cyclic loading test with out-of-plane displacement. The conclusions reached are summarized as follows.
1) The stability conditions for BRBs can be expressed by a single equation using a simple hinge model with end springs. This equation covers both design concepts of BRBs discussed in AIJ recommendation 2009.
2) In the cyclic loading tests, specimens with lesser insert length at the restrainer-ends experience overall buckling before achieving stable hysteresis, which is not satisfactory as the standard performance of a BRB. In contrast, specimens with larger insert length showed stable hysteresis up to 3%.
3) The proposed equation explains well the performance of each specimen in the test, and is considered to be valid.
