The Conditional Operator

- Ternary operator (conditional operator):
  - (2 < 3) ? 6 : 7
  - First operand is boolean, second and third have to be of the same “type”
  - If first operand is true, result is second operand
  - If first operand is false, result is third operand

Control Flow in Java

- Conditional execution: if-else
  - Example: checking divisibility
  - Conditional operator (x ? y : z) is a short-hand for simple if-else statements
- Loops (repeated execution)
  - Example: String reversal, Euclid's GCD algorithm
  - for loop, while loop
