ABSTRACT :

There exist many cities in developing countries which are built with minimal seismic considerations. Also, due to the expenses regarding in detailed and analytical identification of such vulnerable buildings and structures in these cities, it seems that a rapid and inexpensive solution for assessment of a general understanding of the vulnerability of such cities is required for disaster management planning. In this regards, in this study a simplified evaluation form was developed in order to assess the key seismic vulnerability parameters of the buildings and structures in city of Gachsaran located along the Zagrous mountain range in Iran. Based on the gathered information, a data bank was created and using the generalized physical vulnerability functions developed for typical Iranian buildings, then a series of scenario base damage maps for the city was created. Using these maps, and available resources, a series of disaster management planning maps were created for different levels of potential hazard. These simplified procedure used for underdeveloped cities such as Gachsaran has established preliminary needs for planners while more sophisticated methods can be utilized. In this paper, method used will be discussed and results obtained will be presented. It is believed; this simple solution can be utilized in similar cases throughout the world.

KEYWORDS: Seismic, Management Planning, Vulnerability, Disaster

1. INTRODUCTION

Iran is a country with high seismicity. There exist many cities and towns around the nation which are built with minimal seismic considerations. Due to the earthquake activity of the country and poor construction, devastating situation are created after each earthquake. To this extend, one can remember the recent earthquakes of northern Iran and Bam earthquake in Kerman province. These quakes caused many casualties and enormous damages, more so creating a major problem in disaster management planning for the officials.

Study of recent earthquakes around the world especially in developing countries and underdeveloped nations also have revealed in similar problems. It seems due to the expenses regarding in detailed and analytical identification of such vulnerable buildings and structures in these cities, a rapid and inexpensive solution for assessment of a general understanding of the vulnerability of such cities is required for disaster management planning.

In this regards, in this study a simplified evaluation form was developed in order to assess the key seismic vulnerability parameters of the buildings and structures in city of Gachsaran located along the Zagrous mountain range in Iran. Figure-1 shows the location of this city in Iran. Based on the gathered information, a data bank was created and using the generalized physical vulnerability functions developed for typical Iranian buildings, then a series of scenario base damage maps for the city was created. Using these maps, and available resources, a series of disaster management planning maps were created for different levels of potential hazard. These simplified procedure used for underdeveloped cities such as Gachsaran has established preliminary needs for planners while more sophisticated methods can be utilized. In this paper, method used will be discussed and results obtained will be presented. It is believed, this simple solution can be utilized in similar cases throughout the world while financial and expertise are being developed for more sophisticated evaluation studies.

Figure 1 Location of City of Gachsaran

2. SEISMICITY OF GACHSARAN

Gachsaran is located in southern section of Iran along the Zagrous mountain Ranges. Figure-2 shows seismicity of the city by indicating study radius. According to hazard study, results of peak ground accelerations are provided in Table-1 [Nateghi, 2004]. As seen, it was concluded that the city is potentially located in high to moderate seismic zone causing concerns for the city officials.

3. EVALUATION FORM

An evaluation form was derived for information gathering of the buildings throughout the city. A quick study of literature revealed many forms and recommendations for rapid visual screening techniques. In this study ATC, FEMA, Canadian Forms, Yugoslav Forms and Iranian Forms were studied. Based on these forms and construction techniques used in the region, a simple form was devised. Main questions in these forms consist of questions regarding; general information, structural types and deficiencies, soil conditions, number of stories, pounding possibilities and irregularities as well as questions concerning disaster management plans. Numbering techniques was used for the evaluation. These values were selected from FEMA recommendations also were calibrated to the local conditions as shown in the form.

4. DATA COLLECTION

A team of 12 civil engineering local college students were selected and trained for the data collection. Two team leaders; graduate earthquake engineering students were selected for training and data processing. Two workshops were conducted for training. City was divided into grids and students were sent to different grids. A form was filled out by the students in accordance to the directions given in the workshops for each building. At the end of each day, students and their forms were collected and placed into a data bank. To minimize personal judgment errors, all gathered data was checked before placing into the bank. A typical filled out form for a typical building of Figure-3 is shown in Figure-4.

Each building was photographed. Deficiencies and degradations were specially photographed. Figures 5 show typical problems encountered throughout the data gathering. More than 10,000 buildings were studied by this team in less than a month. Use of data bank also enabled the investigators to derive in different enquires. These inquire also provided a closer look at the city's construction and its deviations from the local building code (Iranian Seismic 2800 Standard). Table-2 shows some of the results provided in table form. [Nateghi, 2006] and [Dehghani, 2004].

5. DEVELOPMENT OF VULNERABLITY AND DISASTER MANAGEMENT PLANNING MAPS

After collecting more than 10,000 data forms and creating a data bank, information gathered then was applied to generate the vulnerability and disaster management planning maps. Three levels of vulnerability were defined namely, red, yellow and green indicating very vulnerable, moderately vulnerable and relatively safe buildings. These Maps are shown in Figures 6 to 7. Based on these potentially vulnerable zones and resources available such as hospitals, fire stations, water tanks, food storage and... a generalized disaster planning map was derived as shown in Figure-10. This map has created enough information for the planners to work around the subject while more sophisticated techniques of evaluation can be devised. As shown, different locations are specified for different plans such as temporary shelter and so on.

6. CONCLUSIONS

A city with 15,000 buildings has been evaluated for potential seismic hazard using simple evaluation technique by the help of 12 college students. This technique used qualitative procedure by data gathering and visual screening methods. It is true that the technique used, possess some errors, however for cities and towns that lack enough financial resources or technical expertise, it promises quite sufficient planning tools. It seems that city planners can work with these preliminary maps to develop their strategic plans while waiting for more resources for better estimate of their vulnerabilities and need assessment. Many under privileged cities and towns throughout the world can benefit from this simple form of evaluation especially for the planning phase.
