SHEAR AND TENSILE STRENGTH OF EXPANSION ANCHOR

Yasushi SHIMIZU

Department of Architecture, Faculty of Engineering, Tokyo Metropolitan University, Setagaya-ku, Tokyo, Japan

SUMMARY

In case of enlargement of buildings or seismic retrofitting of existing buildings, expansion anchor are frequently used. However, there are neither industrial standard of the anchors nor reliable design calculation method. Shear test on 48 specimens and pull-out test on 407 specimens of expansion anchor of several types are reported. Improved expansion anchors in which no thread comes to boundary surface are ductile for shear, but some of previous equations give much higher strength than test results on the anchors.

INTRODUCTION

Recently a number of existing building of reinforced concrete in Japan are improved in their performance against earthquakes. In order to increase their strengths or ductilities installing in-filled walls or reinforcing of columns is done. One of the important problems on those works is detail of joint between new concrete and existing old concrete. Expansion anchors are installed in the old concrete and new concrete is poured. In order to design the expansion anchors, Ref.1 was published in which design by analysis and design by testing were shown. In the design by analysis, tensile strength shall be decided by the strength of anchor steel so that the pull-out strength of concrete calculated based on tensile strength of concrete acting on the projected area of stress cone shall be greater than the strength of steel. Shear friction strength is applied to the shear strength of the boundary with anchors. Cyclic behaviors of the joint subjected to shear, however, have not been studied so much. And tension behavior of the anchor is a problem, because a lot of field test show considerablly lower strength than strength of steel and concrete pull-out strength. These two points are the objectives of this study.

SHEAR TEST

Test Specimen Expansion anchors adopted in the specimens are shown in table 1 and Fig.1. Specimens of the shear test are shown in Fig.2. Mechanical properties of materials for shear test specimens are listed in Table 2. Parameters in 83-A are spiral reinforcement and loading history, and parameters in 83-B are types of anchor and loading history. Parameters of 84 are types of anchor sizes, scratching and loading history. Scratching was done with pick-hammer on the face of old concrete. It is commonly specified to do in practical work of seismic retrofit.

(Anchor adopted in the specimens)

Expansion Anchor 1: An anchor with female screw is knocked into bore hole, then the cone expand the tip of the bolt. Entire length of the bolts is embeded into existing concrete. Male bolt is screwed into the anchor in order to connect old and new concretes. So threaded portion of the male bolt comes at the boundary surface.

Expansion Anchor 2: To avoid threaded portion of bolt at the boundary surface long anchor bolt embeded in old concrete for only half of its length was designed by Saito et al. (Ref.4)

: After polyester enclosed in a capsule is inserted into bore hole, a turning reinforcing bar or a entire threaded bolt is inserted so that the capsule is broken and the polyester is mixed to be hardened.

Mortar Anchor : Reinforcing bar is inserted bore hole grouted with fresh mortar.

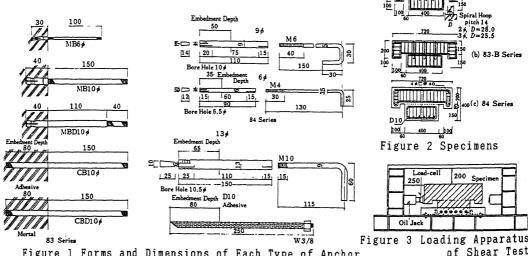

Figure 1 Forms and Dimensions of Each Type of Anchor

<u>Loading Apparatus</u> Loading set-up for shear test is shown in Fig.3. Center line of horizontal loading jacks coincided to the center line of the boundary surface of the specimen. Lateral relative displacements (shift displacements) and vertical relative displacements were measured by means of electric transducers.

Test Results and Calculated Values

Several formulae for design calculation or predicting the shear strength of the joints are listed in Fig.4 in which mutual relationship between calculated values by those formulae is shown. The maximum shear forces of test results were compared with calculated values by means of those formulae in Fig.5. In these figures, correlation coefficient, standard deviation, average of ratio of shear strength to calculated ones and the number of data are shown. In general the calculated values by Eq.Q13 and Eq.Q5 are lower than the experimental values. In these figures most data are in the safety zone. The mean value of the ratios of the maximum shear forces obtained by the tests to the calculated values by Eq.Q12 was 0.9, but the data in this figure are very widely scattered. This formula roughly predicted the test results. The correlation coefficient of the relationship on Eq.Q5 is 0.87, and standard deviation is 0.12. The calculated value by Eq.Q5 predicted the test values fairly well.

The Equations to be used in the	cald	nulation
the Equations to be used in the	car	Julation
$Q1 = a \cdot \sigma m / \sqrt{3}$	(1)	(Ref.1)
$Q2 = 0.4$ aa $\sqrt{Fc \cdot Ec}$	(2)	(Ref.1)
$Q3 = 0.225$ aa $\sqrt{Fc \cdot Ec}$	(3)	(Ref.2)
$Q4 = 0.85 \mu \cdot \sigma y \cdot a a$	(4)	(Ref.3)
Q5 = A w (4.5 ps + 6.7)	(5)	(Ref.4)
Q6 = A w (17.2 ps + 6.53)	(6)	(Ref.5)
$Q7 = A w (0.0101 ps \cdot \sigma y - 2.09)$	(7)	(Ref.6)
$Q8 = 0.5$ aa $\sqrt{Fc \cdot Ec}$	(8)	(Ref.7)
$Q9 = 1.3 Da^2 \sqrt{\sigma y \cdot Fc}$	(9)	(Ref.8)

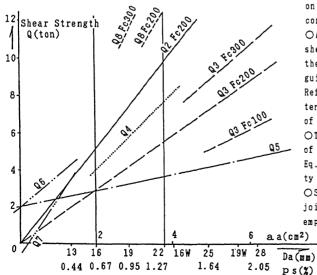

Figure 4 Mutual Relationship among Calculated values

Note
aa: sectional area of steel (anchor),
om,oy: maximum, yielding strength of
steel (anchor),

: the coefficient of friction (=1.0),
Aw: area of boundary, Aw = lw·t
lw: length of boundary, t: thickness
of boundary,

ps : ratio of total cross sectional area
 of anchor to that of boundary,
 ps = 100 aa /(P·t)

(cf.Eq.5 : 0.4<ps <1.0)
P: pitch of anchor

Fc, Ec : strength and modulus of elasticity of concrete

OThe Eq.8 proposed by W. Fisher et al. on shear strength of the boundary with connectors is often used.

OAccording to yield criteria by Von Mises shear strength of ductile steel is 1/3 of the tension strength. The most popular guideline for seismic retrofit in Japan Ref.1 adopted that criteria but maximum tension strength, σ m, was used instead of tension yield strength there.

OThe Eq.8 was proposed for calculation of stud connector. The Ref.1 adopted this Eq. for design of joint, multiplying safety factor 0.8.

OSaito et al. published test results on joint with expansion anchor and proposed empirical formula Eq.5.

(assumption of calculation) t = 200 cm P = 150 cm Ec = 2.1x10⁵ kg/cm²

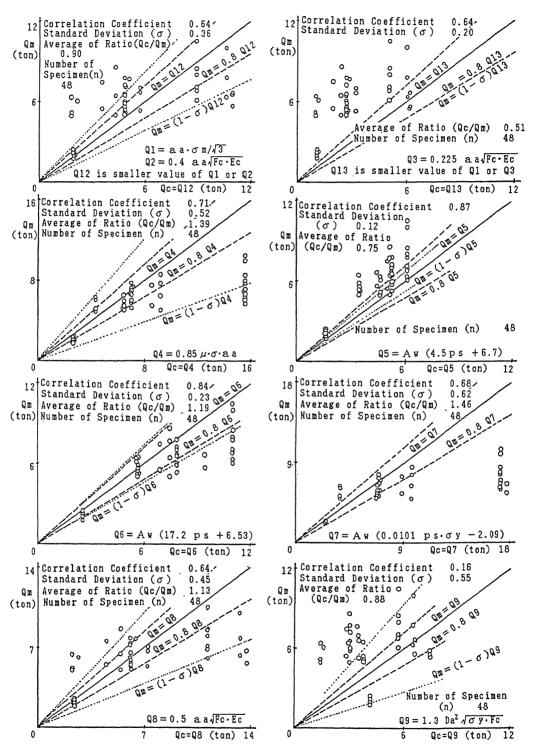

Figure 5 Relationships between Calculated values and Test Result of Shear Test

PULL-OUT TEST

 $\underline{\text{Test}}$ $\underline{\text{Specimen}}$ The detail of specimen and anchor adopted in this test are shown in Fig.6 and Table 3. The anchors tested are 407, and main variables in this test are types of anchor, sizes, concrete strength, distance from concrete edge.

Loading Apparatus The test arrangement of the pull-out test is shown in Fig.7. To investigate the tensile behavior of these expansion anchors, each of them was subjected to static tensile loading. The pulling out displacements at the lower part of the tension bar were measured using displacement transducers.

Test Results and Calculated Values

The test results of the pull-out strength are compared with calculated ones by means of several formulae for predicting the maximum pull-out load. The relationship between the measured pull-out strength and calculated ones are shown in Fig.8 respectively. In the relationship between the calculated values by Eq.P1 and the test results, general measured strengths are lower than the calculated ones. In the figure of relationship between the calculated values by Eq.P2 and the pull-out strength obtained from the test, most data are in the safety zone. The mean value of the ratio of the measured pull-out strength to the calculated values by Eq.P4 is closed to 1.0. The most popular guideline for seismic retrofit Ref.1 adopted the Eq.P1 but the measured pull-out strength of so many data are lower than the calculated ones.

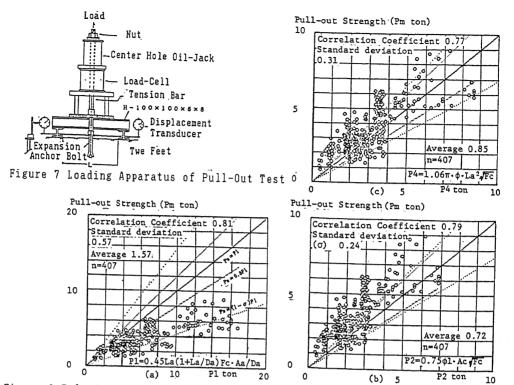

Figure 8 Relationshipsbetween Calculated Values and Test Results of Pull-Out Test

CONCLUDING REMARKS

The design shear strength for anchors are usually based on Ref.7 in Japan. Depend on our experiment, however, this design formula roughly predicted the test results. The figure of the relationship between the test results and calculated ones by Eq.Q8 shows the wide scattering. In the figure on Eq.Q5, most data are in the safety zone.

The design pull-out strength for expansion anchors are usually based on an uniform tensile stress acting on an effective stress area defined as the projected area of stress cones radiating toward the attachment from the bearing edge of the anchors. Depend on our experiment this design are apt to get an upper-bound value.
